American National Election Studies (ANES)

March 19, 2024

## **User's Guide**

### **1. Suggested Citation**

American National Election Studies. 2024. ANES 2024 Pilot Study [dataset and documentation]. March 19, 2024 version. [www.electionstudies.org](http://www.electionstudies.org)

### **2. Study Overview**

The ANES 2024 Pilot Study is a cross-sectional survey conducted to test new questions under consideration for potential inclusion in the ANES 2024 Time Series Study and to provide data about voting and public opinion in the United States. Highlights include:

Title:	ANES 2024 Pilot Study
Data status:	Public release
Main purpose:	To test questions for inclusion in the ANES 2024 Time Series study
Population:	U.S. citizens aged 18 or older
Sample:	Opt-in online panel, cross-sectional design; see Sampling and Weighting section
Mode:	Internet
Number of cases:	1,500 weighted (and 419 additional; see below)
Field period:	February 20 – March 1, 2024
Response rate:	Not meaningful for this sample design
Interview length:	Median 27.5 minutes
Weight:	Use the variable “weight” or “weight_spss” to generalize to the population; see the Sampling and Weighting section below
Sponsors & design:	The National Science Foundation funded the study, which was designed by the ANES Principal Investigators and senior staff
Data collection firm:	YouGov

---

<sup>1</sup> Acknowledgments: The study was designed by Principal Investigators Nicholas Valentino (University of Michigan) and Shanto Iyengar (Stanford University), Associate Principal Investigators Daron Shaw (University of Texas, Austin), Sunshine Hillygus (Duke University), Co-Investigator Matthew DeBell (Stanford University), Rachel Smilan-Goldstein (Stanford University), and Lauren Guggenheim (University of Michigan). The study was funded by the National Science Foundation with a grant to the University of Michigan (grant no. SES-2209438). Any opinions, findings, or recommendations do not necessarily reflect the views of the National Science Foundation. Data collection was performed by YouGov. Portions of this document reprint portions of prior ANES documentation.

### 3. Case Count

There are 1,500 weighted cases on the file and an additional 409 unweighted cases not intended for population inference. The weighted cases are intended to represent the population. The 1,500 weighted cases completed the questionnaire, passed a quality control check by YouGov, and were selected using the sample matching procedure described below in the Sampling and Weighting section. The additional 409 cases are described below and include 296 partial interviews and 113 people who completed the questionnaire but were not selected using the sample matching procedure. The additional cases are included to allow methodological analysis, such as a review of the randomization used in question wording experiments. Weights are not provided for the additional 409 cases, as they are not intended to contribute to population inference. The unmatched cases can be distinguished from the main cases by their missing weights in the `weight` variable or using the variable `sample_type`.

### 4. Recommendations for Analysis and Reporting of Non-probability Sample Data

ANES recommends that:

- the sample should be described as follows:  
*"The survey was conducted using non-probability sampling. This method produces a sample that looks similar to a probability sample on the matched characteristics but may still differ in unknown ways on unmatched characteristics."*
- any analysis intended to make population inferences should be weighted; and
- any use of statistics or terms related to "standard error" or statistical significance in these data should note that these terms are not being used in their ordinary sense but are being applied in the context of a non-probability sample.

See the Sampling and Weighting section below for an elaboration on these recommendations.

### 5. Sampling and Weighting

The study was conducted on the Internet using the YouGov panel. The YouGov panel consists of a large and diverse set of over a million respondents who have volunteered to complete surveys online and who regularly receive invitations to do so. They receive points usually worth **about** 30 to 50 cents for each survey they complete. The points are redeemable for various gift cards. A respondent has to complete about 40 surveys to be eligible for any reward.

Respondents were selected from the YouGov panel by sample matching. Matching is intended to make the individuals who complete the survey represent the population on the variables used for matching. YouGov describes their procedure as follows:

The respondents were matched to a sampling frame on gender, age, race, and education. The sampling frame is a politically representative "modeled frame" of US citizens, based upon the American Community Survey (ACS) public use microdata file,

public voter file records, the 2020 Current Population Survey (CPS) Voting and Registration supplements, the 2020 National Election Pool (NEP) exit poll, and the 2020 CES surveys, including demographics and 2020 presidential vote. The matched cases were weighted to the sampling frame using propensity scores. The matched cases and the frame were combined and a logistic regression was estimated for inclusion in the frame. The propensity score function included age, gender, race/ethnicity, years of education, home ownership, and region. The propensity scores were grouped into deciles of the estimated propensity score in the frame and post-stratified according to these deciles. The weights were then post-stratified on 2020 presidential vote choice as well as a four-way stratification of gender, age (4-categories), race (4-categories), and education (4-categories), to produce the final weight.

*Respondents opt-in to YouGov's panel.* It is conventional to refer to datasets from opt-in panels as “nonprobability samples.”

*The basis for population inference: an assumption of conditional ignorability.* Matching the YouGov sample data against high-quality data sources and additional weighting of the data enable inferences with respect to the population, under an assumption of conditional ignorability or “selection on observables,” i.e., given the variables used in weighting and matching, survey participation is independent of variables measured in the survey. The assumption is, in other words, that after controlling for the matching and weighting factors (gender, age, race/ethnicity, education, geographic region, and presidential candidate choice), participation or non-participation in the survey is not systematically related to any of the other survey questions. If this assumption holds, a useful consequence is that the sample distribution of survey variables will (at least approximately) match the distribution of those variables in the population; matching helps ensure that this is true not just for marginal distributions, but for joint distributions of survey variables. The applicability of the conditional ignorability assumption to non-probability survey samples is controversial in the research community.<sup>2</sup>

*Statistical significance and “standard errors.”* Standard errors are measures of variability in sample statistics (estimates of population parameters) arising from random sampling. The design of a sampling plan determines the way a standard error is computed, most typically by accounting for different probabilities of selection for sampled units (e.g., contrast simple random sampling versus complex sampling designs). Because the YouGov survey data were not generated by a probability sampling plan, some practitioners recommend against using the term “standard error” (and related terms such as “sampling error,” “margin of error,” and “confidence intervals”) when reporting analyses of these data,<sup>3</sup> at least without noting that

Pew Research Center, online at <http://www.pewresearch.org/2016/05/02/evaluating-online-nonprobability-surveys/>

<sup>3</sup> See Baker, Reg, et al. 2010. AAPOR Report on Online Panels. *Public Opinion Quarterly* 74, 711-781, and Baker,

these terms are not being used in their usual sense. Valid inference of any “standard error” reported for these data rests on the ignorability assumption noted above.

*Weights in data analysis.* The variable called “weight” on the ANES 2024 Pilot Study data file is the weight for analysis that is intended to generalize to the population. ANES strongly recommends using the weights provided with this data set when making inferences about the target population of U.S. adult citizens.

This weight variable is normalized to have a mean of 1.0, such that the number of weighted observations equals 1,500. The weight variable ranges from 0.31 to 7.0 and has variance 0.220. Using this weight variable means that the resulting standard errors and confidence intervals will be larger than those from analyses that naively treat the data as a simple random sample (but SPSS users and other users of frequency weights should see the note below on “SPSS weights”.) With a simple random sample of 1,500 observations, a sample estimate of a proportion of .5 would have a standard error of 0.012 and a 95% confidence interval of +/- 0.0238. In this data set, the weights result in a loss of precision relative to a simple random sample by a factor proportional to the variance of the weights (recall that under simple random sampling, any weight variable would be constant and have variance zero); standard errors and confidence intervals are inflated by a term proportional to the standard deviation of the weights.

In the current dataset, the pseudo-design effect due to weighting is 1.2198, and the root design effect is 1.1044. This means that, provided that the ignorability assumption noted above holds true, the sample’s statistical power is equivalent to a simple random sample size of  $1,500/1.2198 = 1,230$ , and the expected pseudo-sampling error (which is, again, not a conventional sampling error because this is not a probability sample) for an estimated proportion of .5 would be increased by a factor of 10.4% ( $0.012 \times 1.1044$ ) to 0.0133.

*SPSS weights.* We recommend that SPSS users not using the Complex Samples procedures use the weight variable `weight_spss`, which is normed to a mean of  $1,230/1,500 = 0.82$ . This variable will account for the smaller effective sample size. When not using the Complex Samples procedures, it is appropriate to use this adjusted weight because SPSS uses frequency weights that do not account for the variance of the weights when computing standard errors.

*Sample dispositions.* YouGov invited 6,597 of their panelists to answer the questionnaire. Of these, 3,520 did not respond and 3,077 made some initial response. Of the 3,077 who responded to the invitation, 809 were screened out without completing the interview (including 801 who failed initial quality or attention checks before starting the survey and 8 who did not meet demographic or eligibility requirements) and 359 completed the interview but were rejected by YouGov on quality control grounds (such as completion time and item nonresponse). The remaining 1,909 cases are included in the data file and consist of 296 partial

---

Reg, et al., Report of the AAPOR Task Force on Non-Probability Sampling. AAPOR 2013. Available at [https://www.aapor.org/AAPOR\\_Main/media/MainSiteFiles/NPS\\_TF\\_Report\\_Final\\_7\\_revised\\_FNL\\_6\\_22\\_13.pdf](https://www.aapor.org/AAPOR_Main/media/MainSiteFiles/NPS_TF_Report_Final_7_revised_FNL_6_22_13.pdf)

interviews (considered breakoffs and not weighted), 113 complete interviews that were not sample-matched, and 1,500 weighted cases that were selected using the matching procedure described above. As described in the Case Count section above, the data from the 409 cases that were not selected (296 partials and 113 complete but unmatched) are included in the data file but are not weighted and should not be used in analyses intended to represent the population. Weighted analysis will automatically select the correct cases for population inference.

## **6. Programming error**

Respondents were asked to rate “pro-life activists” on a feeling thermometer. Where this was the eligible group with the lowest feeling thermometer rating (or the randomly selected group of multiple groups with the lowest rating), the group name was displayed in one of two tolerance batteries, *tolnew* or *tolold*. Where this group was intended to be displayed, it was misspelled as “pro-lift activists.” This affected 27 respondents.

## **7. Codebook**

The remainder of this document consists of the codebook that describes the variables appearing in the dataset.
