

Codebook and User's Guide for the ANES 2020 Social Media Study

American National Election Studies

Stanford University & the University of Michigan

March 8, 2021

1. Study Overview

The ANES 2020 Social Media Study is a two-wave panel survey conducted on the Internet to provide data about voting and public opinion in the 2020 presidential election and to link these survey data with data downloaded from participants' Facebook accounts. The two-wave design mirrors the ANES Time Series design, with pre-election and post-election questionnaires. This release contains survey data only; data from the linked Facebook accounts will become available in the future.

Though the study features pre-election and post-election surveys, this study should not be confused with the ANES 2020 Time Series Study, which also includes pre- and post-election surveys on the Internet with a higher response rate, different and longer questionnaires, and a different and larger sample than this study.

Title:	ANES 2020 Social Media Study
Data status:	Combined pre-election and post-election survey data are provided
Dataset version:	This documentation accompanies the March 8, 2021 version of the data (20210308).
Main purpose:	To link pre- and post-election survey data to Facebook account data
Population:	U.S. citizens age 18 or older (including Facebook users and non-users)
Sample:	Online panel using probability sample
Response rate:	3.2 percent overall (pre-election)
Mode:	Internet
Number of cases:	5,750 pre-election, of which 5,277 also completed post-election
Field period:	Pre-election: August 20 through September 17, 2020 Post-election: November 1 through January 1, 2021
Interview length:	Median 23 minutes pre-election and 23 minutes post-election
Weight:	For analysis of pre-election data only, use the variable "weight_pre" to generalize to the population. For pre- and post-election combined or post-election data only, use "weight_post". See part 3 below.
Sponsors & design:	The study was funded by a gift to Stanford University from Facebook and by a grant from the National Science Foundation, and was designed by the ANES Principal Investigators, ANES Board members, advisory committee for this study, ¹ and senior staff.
Data collection firm:	NORC at the University of Chicago

2. Forthcoming Additional Data

¹ The committee to advise the Principal Investigators for this questionnaire was composed of John Aldrich, James Druckman, Leonie Huddy, Gary Jacobson, Jaime Settle, Stuart Soroka, and Michael Traugott.

This release of the data replaces the initial dataset released on January 28, 2021. It includes the pre-election and post-election survey data; it does not include data from linked Facebook accounts, which will be provided in the future using a separate process.

With this special study, quality control review and error correction have not been provided to the same standard as with a final data release of an ANES Time Series study. Future re-releases of the data may include some changes to the data, such as error corrections, to improve accuracy or usability. ANES always wants to correct errors. If you find errors (even years after this data release) or have comments or questions about the data, please let us know by writing to anes@electionstudies.org

Data from participants' Facebook profiles will become available through a separate special-access procedure that will be announced in the future. The expected Facebook profile data include the participant's frequency of Facebook use, political ads seen, shared, or liked by the participant, the content of posts naming presidential candidates, URLs in the participant's Facebook news feed, and actions the participant took with the links such as sharing or liking.

3. Sampling, Response Rate, and Weighting

The study was conducted on the Internet using an online survey panel that was selected using probability sampling methods. This sample was provided by NORC at the University of Chicago.

The study's target population was U.S. citizens age 18 or older. The sample was stratified by previously reported Facebook user status, race/ethnicity, age, education, and gender. Completion targets were established, and once the target number of Facebook users had completed the questionnaire, additional self-reported Facebook users were screened out.

The weighted household recruitment rate was 21 percent, reflecting the percentage of households where an adult was enrolled in the panel and completed a recruitment questionnaire. The retention rate from the time of initial recruitment to the time the sampling was done for this survey was 80.4 percent. A sample of 31,043 individuals was initially invited to participate in this survey. Of those invited, 35.2 percent completed a screening step that ascertained their U.S. citizenship status, obtained informed consent for the study, and determined whether they were or were not a Facebook user. Of those screened, 98.6% were eligible for the study, and 53.3 percent of those eligible completed the study. The overall response rate is the product of the recruitment, retention, screening, and completion rates, and was 3.2 percent. The post-election re-interview rate was 91.8 percent.

Weights. The variables `weight_pre`, and `weight_post` were developed by NORC to account for selection probability, nonresponse (in categories of Facebook user status, 2 race categories, 3 age categories, 2 education categories, and 2 gender categories), and post-stratification factors (7-category age, 2-category gender, 9-category census division, 4-category education, 4-category race/ethnicity, and an 8-category interaction term of age

and gender, age and race, and race and gender). Post-stratification was based on benchmark values for adult U.S. citizens from the American Community Survey. The post-election weight was trimmed by ANES to a maximum value of 5 to limit variance. The pre-election weight should be used for analysis of the pre-election data alone. The post-election weight should be used for analysis of the pre- and post-election data together or of the post-election data alone.

The pre-election weighted design effect is 1.52; the root design effect is 1.23. This means that the sample's average statistical power is equivalent to an unweighted simple random sample size of $5750/1.52 = 3,783$, and the expected sampling errors are increased by a factor of 1.23 relative to what would be expected of a sample of 5750. The post-election design effect is 1.63 and the post-election root design effect is 1.28. Note that design effects vary and will be larger or smaller for some estimates.

SPSS weights. We recommend that SPSS users not using the Complex Samples procedures use the weight variables `weight_pre_spss`, and `weight_post_spss` which are normed to means of 0.66 and 0.61, respectively. These variables will account for the smaller effective sample size due to sampling and weighting. When not using the Complex Samples procedures it is appropriate to use these adjusted weights because SPSS uses frequency weights that do not account for weight variance when computing sampling errors.

Weights without post-stratification. The variables `weight_pre_nr` and `weight_post_nr` account for selection probability and non-response but are not post-stratified or scaled to a mean of 1. They are included for methodological purposes such as re-weighting the data using different approaches to post-stratification.

4. Cases on the File

Data from 5,750 completed pre-election interviews are on the file. An additional 80 participants completed the questionnaire but their data failed a quality-control check performed by NORC. Data from these cases were considered invalid and they were not weighted and were excluded from the data file due to item nonresponse (they did not answer more than 50% of the questions they were asked), speeding (they completed the questionnaire 33% faster than the median time), or nondifferentiation/straightlining (they selected the same response for all grid items).

Data are provided for 5,277 post-election interviews. An additional 52 participants completed the post-election questionnaire but their data failed a quality-control check of the type described above. For questionnaire variables these cases have the same unit non-response code as cases of post-election unit nonresponse, but they are identified by the variable `w2qual`.

5. Dataset Variables

There are 519 variables on the file.

The first variable, “version” indicates the dataset version and date it was produced by ANES.

“caseid” uniquely identifies each case. This variable is numbered from 1 to 5,830, but there are only 5,750 cases on the file; the omitted numbers are cases that were dropped due to invalid data.

“w2qual” indicates the post-election status of each case.

“weight_pre” is the post-stratified pre-election analysis weight, “weight_pre_nr” is the pre-election weight without post-stratification, and “weight_pre_spss” is a version of weight_pre scaled to produce generalized variance estimates when used with frequency weights. The variables “weight_post,” “weight_post_nr,” and “weight_post_spss” are corresponding weights for the post-election data.

Variables in positions 10 through 50 are profile items usually asked prior to the ANES questionnaire.

Variables in positions 51 and 52 are the Congressional District of the participant’s residence, based on information in the NORC panel database, as applicable at the times of the pre- and post-election surveys, respectively.

Variables 53 through 58 concern the administration of the study and provide the starting and ending date and time, duration in minutes, mode, language, and type of device used to take the pre-election survey.

Variables 59 through 68 are preload data for values defined in the pre-election questionnaire specifications. In several cases these are randomization variables for inclusion or exclusion of questionnaire modules.

Variables 69 through 279 apply to the pre-election instrument and are of four types: questionnaire variables, timing variables indicating the elapsed time to complete a section of the questionnaire, position variables indicating randomized question or response option order, and calculated summary variables for party identification or political knowledge. The calculated variables are located ahead of their corresponding questionnaire items.

Variables 280 through 285 are administrative variables for the post-election survey, equivalent to those in positions 53-58 for the pre-election survey.

Variables 286 through 298 are preload data for values defined in the post-election questionnaire specifications.

Variables 299 through 519 are post-election variables equivalent to those in positions 69-279 for the pre-election data.
